## \MRI Primer, Exercise \#7 <br> Solution

## Question 1

The signal at the echo time, as derived in class $\&$ in the notes, is given by

$$
\mathrm{M}_{\mathrm{xy}}(\mathrm{r})=\left[1-\mathrm{e}^{-\mathrm{TR} / \mathrm{T}_{1}(\mathrm{r})}\right] \mathrm{e}^{-\mathrm{TE} / \mathrm{T}_{2}(\mathrm{r})} \mathrm{M}_{0}(\mathrm{r})
$$

The difference in this intensity between two types of tissue, differing only in their $T_{1}$, is given by

$$
\begin{aligned}
\mathrm{M}_{\mathrm{xy}}^{(2)}(\mathrm{r})-\mathrm{M}_{\mathrm{xy}}^{(1)}(\mathrm{r}) & =\left[\left(1-\mathrm{e}^{-\mathrm{TR} / \mathrm{T}_{1}^{(2)}(\mathrm{r})}\right)-\left(1-\mathrm{e}^{-\mathrm{TR} / \mathrm{T}_{1}^{(1)}(\mathrm{r})}\right)\right] \mathrm{e}^{-\mathrm{TE} / \mathrm{T}_{2}(\mathrm{r})} \mathrm{M}_{0}(\mathrm{r}) \\
& =\left(\mathrm{e}^{-\mathrm{TR} / \mathrm{T}_{1}^{(1)}(\mathbf{r})}-\mathrm{e}^{-\mathrm{TR} / \mathrm{T}_{1}^{(2)}(\mathbf{r})}\right) \mathrm{e}^{-\mathrm{TE} / \mathrm{T}_{2}(\mathrm{r})} \mathrm{M}_{0}(\mathrm{r})
\end{aligned}
$$

To maximize this, we need to find

$$
\frac{\mathrm{d}\left(\mathrm{M}_{\mathrm{xy}}^{(2)}(\mathrm{r})-\mathrm{M}_{\mathrm{xy}}^{(1)}(\mathrm{r})\right)}{\mathrm{d}(\mathrm{TR})}=0
$$

We've actually solved this equation in the lecture notes for the $T_{2}{ }^{*}$ case in GRE experiments. The solution is:

$$
\mathrm{TR}_{\text {maximal contrast }}=\frac{\mathrm{T}_{1}^{(1)} \mathrm{T}_{1}^{(2)}}{\left(\mathrm{T}_{1}^{(1)}-\mathrm{T}_{1}^{(2)}\right)} \ln \left(\frac{\mathrm{T}_{1}^{(1)}}{\mathrm{T}_{1}^{(2)}}\right) \approx \frac{\left|\mathrm{T}_{1}^{(2)}+\mathrm{T}_{1}^{(2)}\right|}{2}
$$

## Question 2

The signal at echo time is

$$
M_{x y}(r)=\frac{\left[1-\mathrm{e}^{-\mathrm{TR} / \mathrm{T}_{1}(\mathrm{r})}\right] \sin (\alpha)}{1-\cos (\alpha) \mathrm{e}^{-\mathrm{TR} / \mathrm{T}_{1}(\mathrm{r})}} \mathrm{e}^{-\mathrm{TE} / \mathrm{T}_{2}{ }^{*}(\mathrm{r})} \mathrm{M}_{0}(\mathrm{r})
$$

To maximize it with respect to $\alpha$, we need to find $\alpha$ for which

$$
\frac{\mathrm{dM}_{\mathrm{xy}}}{\mathrm{~d} \alpha}=0
$$

Differentiating (this is a bit cumbersome), we obtain

$$
\frac{\left(1-\mathrm{E}_{1}\right) \cos (\alpha)}{1-\mathrm{E}_{1} \cos (\alpha)}-\frac{\left(1-\mathrm{E}_{1}\right) \mathrm{E}_{1} \sin ^{2}(\alpha)}{\left(1-\mathrm{E}_{1} \cos (\alpha)\right)^{2}}=0, \quad \mathrm{E}_{1} \equiv \mathrm{e}^{-\mathrm{TR} / \mathrm{T}_{1}}
$$

where I've denoted $E_{1}=e^{-T R / T 1}$. Simplifying, we obtain

$$
\cos (\alpha)=\frac{\mathrm{E}_{1} \sin ^{2}(\alpha)}{1-\mathrm{E}_{1} \cos (\alpha)}
$$

Simplifying some more, and using $\cos ^{2}+\sin ^{2}=1$, we get the desired result

$$
\cos (\alpha)=\mathrm{E}_{1} .
$$

So, why isn't the Ernst angle used in MRI? Because, once a sufficient signal magnitude has been attained and you can see what you're after, increasing it further serves no purpose. Your goal in MRI is often maximal contrast, not maximal signal!

## Question 3.

The magnetization is

$$
M_{x y}(z, t)=M_{0} e^{-i \gamma G z t} \quad \text { for }-L / 2 \leq z \leq L / 2
$$

The signal is then

$$
s(\mathrm{t}) \propto \int_{-\mathrm{L} / 2}^{\mathrm{L} / 2} \mathrm{M}_{\mathrm{xy}}(\mathrm{z}, \mathrm{t}) \mathrm{dz}=\mathrm{M}_{0} \int_{-\mathrm{L} / 2}^{\mathrm{L} / 2} \mathrm{e}^{-\mathrm{i} \gamma \mathrm{Gzt}} \mathrm{dz}=\mathrm{M}_{0} \frac{\mathrm{e}^{\mathrm{i} \gamma \mathrm{GLt} / 2}-\mathrm{e}^{-\mathrm{i} \gamma \mathrm{GLt} / 2}}{\mathrm{i} \gamma \mathrm{Gt}}=\frac{\mathrm{LM}_{0}}{2} \operatorname{sinc}\left[\frac{\gamma \mathrm{GLt}}{2}\right]
$$

where I've used $\sin (\mathrm{x})=\left(\mathrm{e}^{\mathrm{ix}}-\mathrm{e}^{-\mathrm{ix}}\right) / 2 \mathrm{i}$. So, the signal decays as follows:

The first 0 of a sinc function is encountered when

$$
\sin c(x)=0 \quad \text { when } \quad \sin (x)=0 \quad \text { when } \quad x=\pi / 2
$$

In our case, $\mathrm{x}=\gamma \mathrm{GLt} / 2$, so the signal becomes 0 (for the first time) when

$$
\frac{\gamma \mathrm{GLt}}{2}=\pi / 2 \quad \Rightarrow \quad \mathrm{t}=\frac{\pi}{\gamma \mathrm{GL}}
$$

For a 30 cm sample, with $G=40 \mathrm{mT} / \mathrm{m}$, one has

$$
\mathrm{t} \approx \frac{1}{2 \times 42 \times 10^{6} \times 40 \times 10^{-3} \times 0.3} \approx 1 \text { microsecond }
$$
